INTRODUCTION

In today's world, health is of prime importance along with all other essential services which help us reduce our stress and workload. Labor comes at a very high value in some countries. Service repairs like RO Repair and refrigerator maintenance often cost a huge sum of money. We are designing a model which will provide all these services at your doorstep. We are designing a service management and service providing system which will make life easier and services cheaper. We like DoorDash, the revered food delivery application, provide options online to book the desired service according to the area code. Certain areas cost more, certain less.

We will be providing a detailed bill online pertaining to the different services chosen and will display the entire amount. The customer has the luxury to decline the service even then. The Customer will have constant monitoring via GPS of where his desired vendor has reached at any point in time. Customer can also choose the total experience of each vendor as we will display that to him while placing an order.

PHENOMENON

Service Provider – Home cleaning and appliances Repair.

INFORMATION SYSTEM

Provide service to the customers for home cleaning and appliance repair on demand based on the area code they reside in and assist them in booking appointment.

BUSINESS PROCESSES

We have enlisted three prime business processes along with many others. I will be explaining the three major business processes and activities in our project.

| Business Process No. | Process Name | Activities | Description |
|----------------------|----------------------------------|------------|---|
| 1 | Customer and Services Management | Activity 1 | Maintain List of customers and services being provided |
| | | Activity 2 | Relate the services selected by the customer and provide recommendations based on it |
| 2 | Operations | Activity 1 | Calculate Revenue monthly for a service and calculating the overall revenue |
| | | Activity 2 | Identify best employees based on ratings |
| 3 | Business Analysis | Activity 1 | Sort the areas based on the number of appointments received from them and make necessary business |

| | | | |
|--|--|------------|--|
| | | | decisions to work on area codes with less appointments |
| | | Activity 2 | Get the list of most popular services based on how many customers opted for a service in given month or year |

Business Process 1 - Customer and Services Management

Here we will work on maintaining a database containing all the services and the list of all the customers who use our product. We would relate the services chosen by each customer frequently which will work as a market basket to enable us to provide us to provide useful recommendations.

Activity 1 – Maintain a list of customers and services chosen.

We will maintain a list of all the customers affiliated to our product.

Business / Functional Requirements – We must develop a list which keeps updating each time customer signs up for any service.

Data Requirements – We will require the name of the customer, age, date of appointment for each customer. We also need to maintain a database of all the services that we offer.

Activity 2 – Relate the services selected by the customer and provide recommendations based on it.

We will maintain a list of all the customers affiliated to our product. We will store the results in our database corresponding the service each customer has selected.

Business / Functional Requirements – We must develop a database of services availed by each customer in one table to help us provide recommendations accordingly.

Data Requirements – We will require the name of the customer, age, date of appointment for each customer. We will also require the services chosen by each customer.

Business Process 2 - Operations

Here we will work on how good or bad the business is doing both financially and service wise. We will classify the best of our employees and reward them for their hard work and skill and at the same time calculate the amount of revenue that we are generating monthly.

Activity 1 – Calculate Revenue monthly for a service and calculating the overall revenue

We will maintain a total revenue bill and with the help of queries calculate the revenue per month and the revenue overall till date. We will try and find out whether any seasonality in the revenue exists.

Business / Functional Requirements – Based on the price of each service we will calculate the total revenue generated by each service which will help us making operational decisions as in which services need more attention and employees.

Data Requirements – We will require the name of the total services provided per month. We also need to calculate the sum of revenue from each service monthly.

Activity 2 – Identify best employees based on ratings

Sincerity and dedication are two important virtues. It is necessary to reward these qualities righteously. We will reward our best rated employees, and this will also enable us to find out which employees will continue making us revenue throughout their tenure.

Business / Functional Requirements – Employee rating will help us analyze performance of each employee and take necessary actions regarding appraisal for best performers and extensive training for weak performers.

Data Requirements – We will require the ratings given by customers to every vendor and the number of times a particular vendor has been chosen.

Business Process 3 – Business Analysis

This will help our business grow. We will have detailed analysis regarding people from which area choose which services. We will also be getting a list of most popular services that are offered by our business. This will help us make strong strategic decisions to expand our business.

Activity 1 – Sort the areas based on the number of appointments.

We need to sort the services used most per area which will enable us to expand our business.

Business / Functional Requirements – Based on the number of appointments received from each area we will make necessary business decisions to work on area codes with less appointments.

Data Requirements – We will need to prepare a table which will indicate the count of appointments per service in an area.

Activity 2 – Identify most popular service

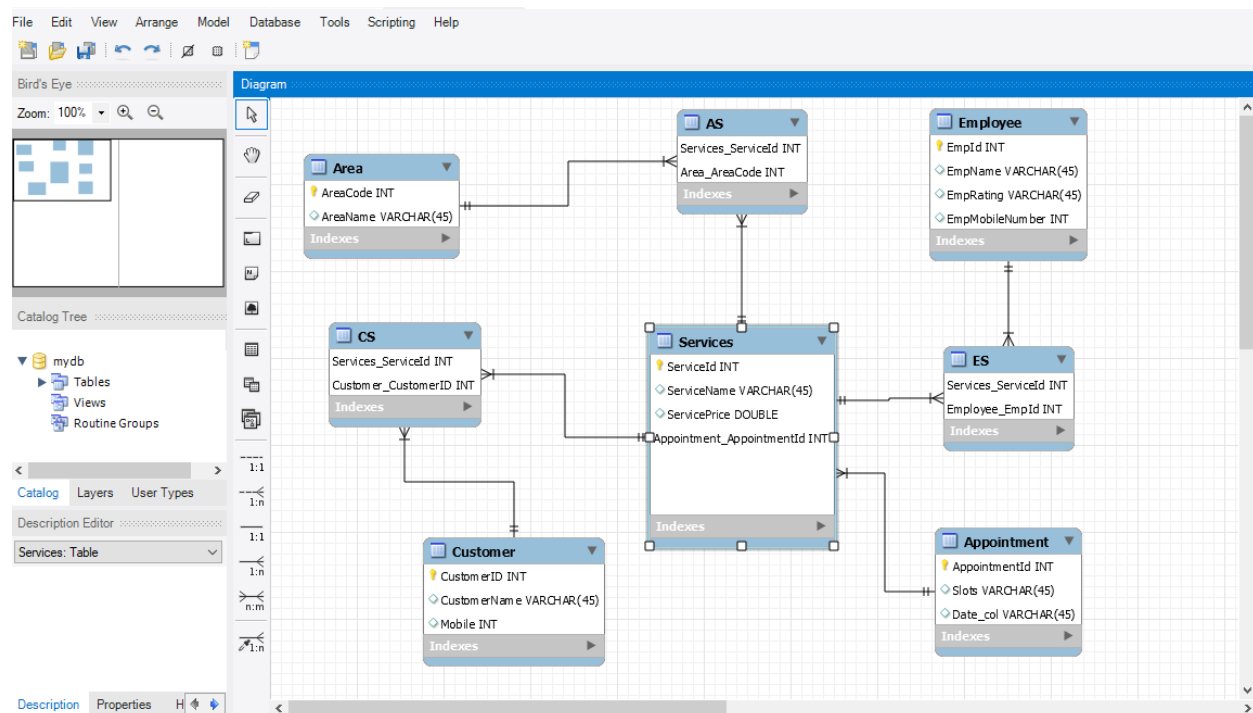

Here we will produce a list of most popular services based on how many customers opted for a service in given month or year.

Business / Functional Requirements – This will enable us to understand which are the services that the customers love. We will then try and provide these services at a cheaper rate to the areas where the business is generating a low revenue.

Data Requirements – We will need to sort our data on a monthly or yearly basis, to find out the count of number of appointments per service to predict the most popular one.

PART 2

THE ERD is as follows

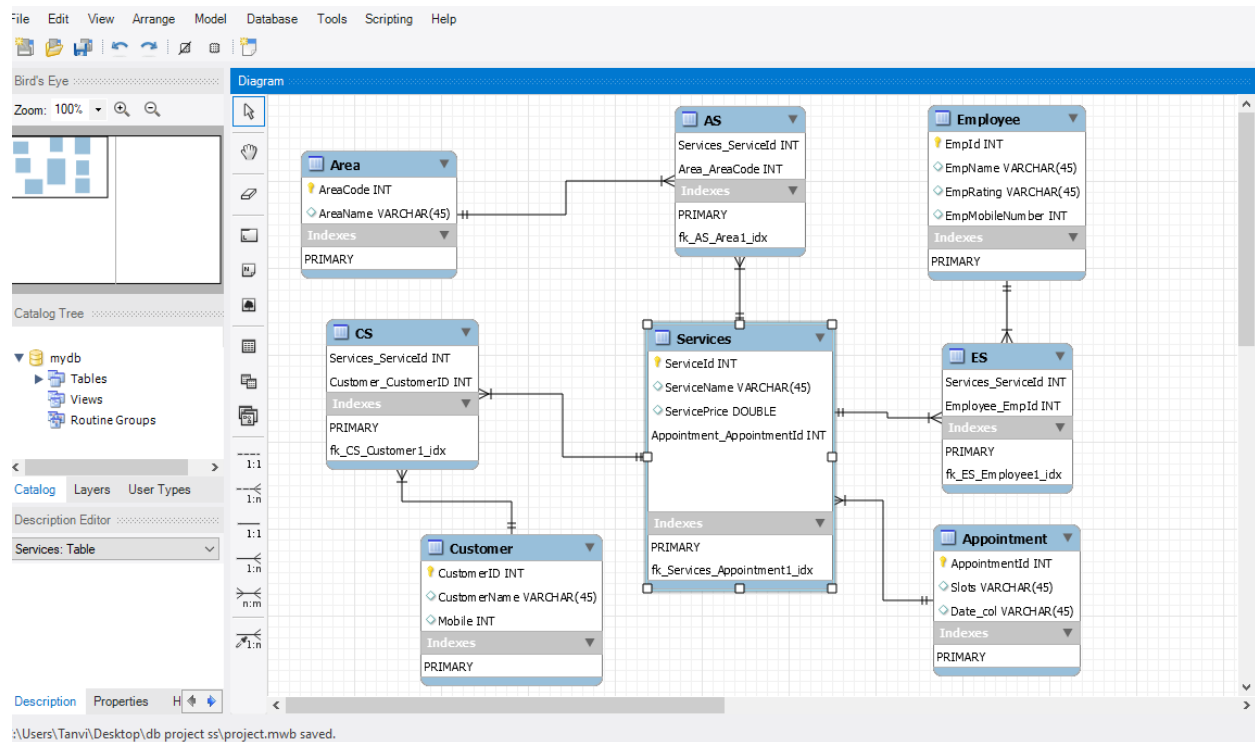

- There is many to many relationship between Area and Service. One Area can have many services and any service can be available in many areas. To resolve this, we have associative entity type which is 'aservice.'
- There is many to many relationship between Customers and Services. One service can be availed by many customers and one customer can avail many services. This is resolved with the help of associative entity type 'cs'.
- There is one to many relationship from Services to Appointment. One Service can be assigned to many appointments however each appointment can be created only for one Service.
- There is many to many relationship from Service to Employees. One service can be assigned to many employees, but one employee can work for many services. This is resolved using the table 'es'.

PART 3

No normalization is required for our database, as all the tables are already normalized. We have used auto incrementing primary keys (integers). Therefore, there will not be a problem of repeated rows.

The relationship diagram from the DBMS is as follows.

We have created a total of 8 tables

Five of which are representing the actual data requirements.

1. Appointment
2. Area
3. Customer
4. Employee
5. Services

The remaining three are produced to link certain tables with each other to maintain cardinality of each table as one to many.

1. Area and Services
2. Customer and Services
3. Employee and Services

PART 4 - Queries

In accordance with our business processes we have designed the following queries.

Query 1

Translation – Here we are querying the data to find out customers who are using a particular service from among all the offered services. We are presenting the data containing columns as ServiceID, ServiceName, FirstName and LastName.

Example – Here we have considered customers availing only the 'RO Repair' Service.

Output produced after executing the query is as follows:

The screenshot displays the SQL Server Enterprise Manager interface. On the left, the 'Navigator' pane shows a tree view of the database schema, including tables like 'appointment', 'area', 'aservice', 'cs', 'customer', 'employee', 'es', 'services', 'sakila', and 'sys'. The 'project_v8' schema is selected. The main pane shows a SQL query in the 'SQL File 8*' editor. The query is as follows:

```
1  ## Query 1 - Display all the customers who opted for the RO service, display their, first and last name along with the  
2  select services.ServiceID, services.ServiceName, customer.FirstName, customer.LastName  
3  from cs, services, customer  
4  where services.ServiceName='RO Repair'  
5  and services.ServiceID = cs.Services_ServiceID  
6  and cs.Customer_CustomerID = customer.CustomerID;
```

Below the query editor, the 'Result Grid' shows the output of the query. The grid has four columns: 'ServiceID', 'ServiceName', 'FirstName', and 'LastName'. The results are as follows:

| ServiceID | ServiceName | FirstName | LastName |
|-----------|-------------|-------------|-----------|
| 5 | RO Repair | Allen | Dan |
| 5 | RO Repair | Yan | Ferry |
| 5 | RO Repair | Sien | Dairy |
| 5 | RO Repair | Mia | Harris |
| 5 | RO Repair | Lakshita | Jenkins |
| 5 | RO Repair | Amey | Perry |
| 5 | RO Repair | Christopher | Lopez |
| 5 | RO Repair | Sofia | Walkar |
| 5 | RO Repair | Elizabeth | Russel |
| 5 | RO Repair | Sarah | Comer |
| 5 | RO Repair | Nishant | Flores |
| 5 | RO Repair | Sofia | Walkar |
| 5 | RO Repair | Sien | Dairy |
| 5 | RO Repair | Lisa | Alexander |
| 5 | RO Repair | Allen | Dan |
| 5 | RO Repair | Yan | Ferry |
| 5 | RO Repair | Sien | Dairy |
| 5 | RO Repair | Mia | Harris |
| 5 | RO Repair | Lakshita | Jenkins |

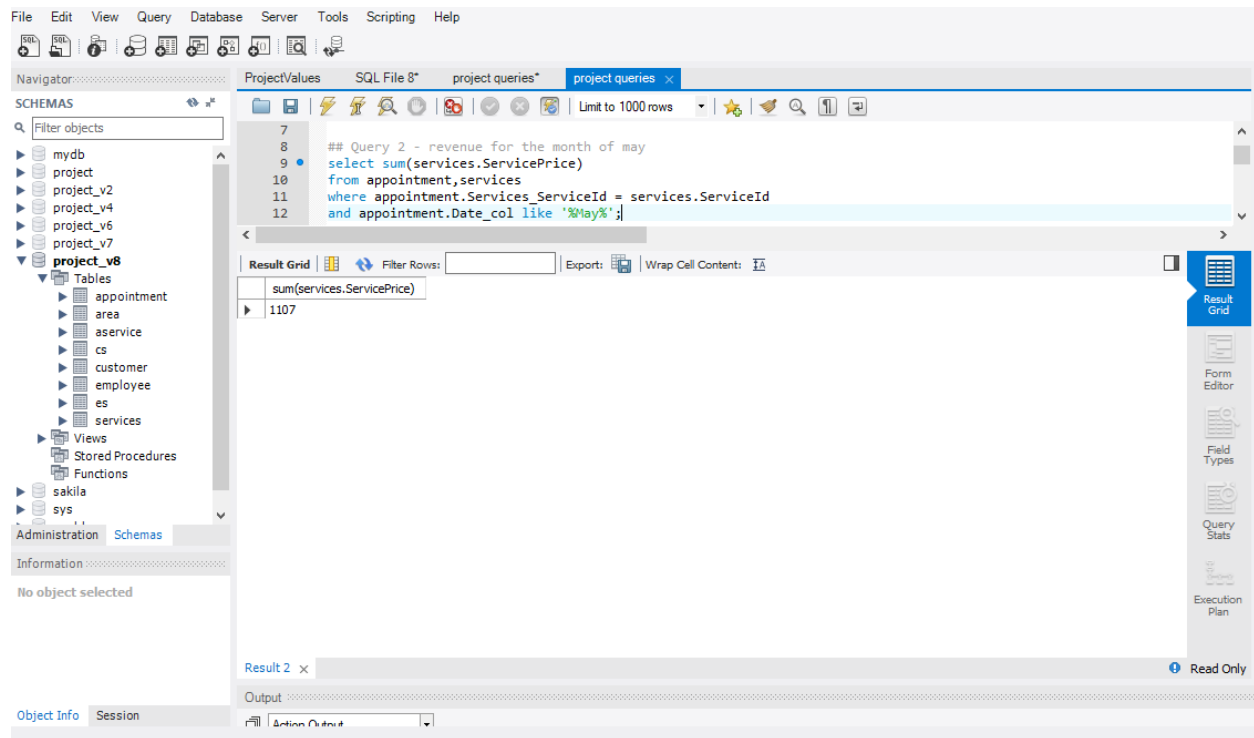

Queries in accordance with business process 2 - Operations

Query 2

Translation – Here we are calculating the total revenue in a month for all the services offered. This is in accordance with activity 1

Example – Here we are only calculating the total revenue for the month of May. We will be using the 'sum' aggregate function

Output generated after executing the query is as follows

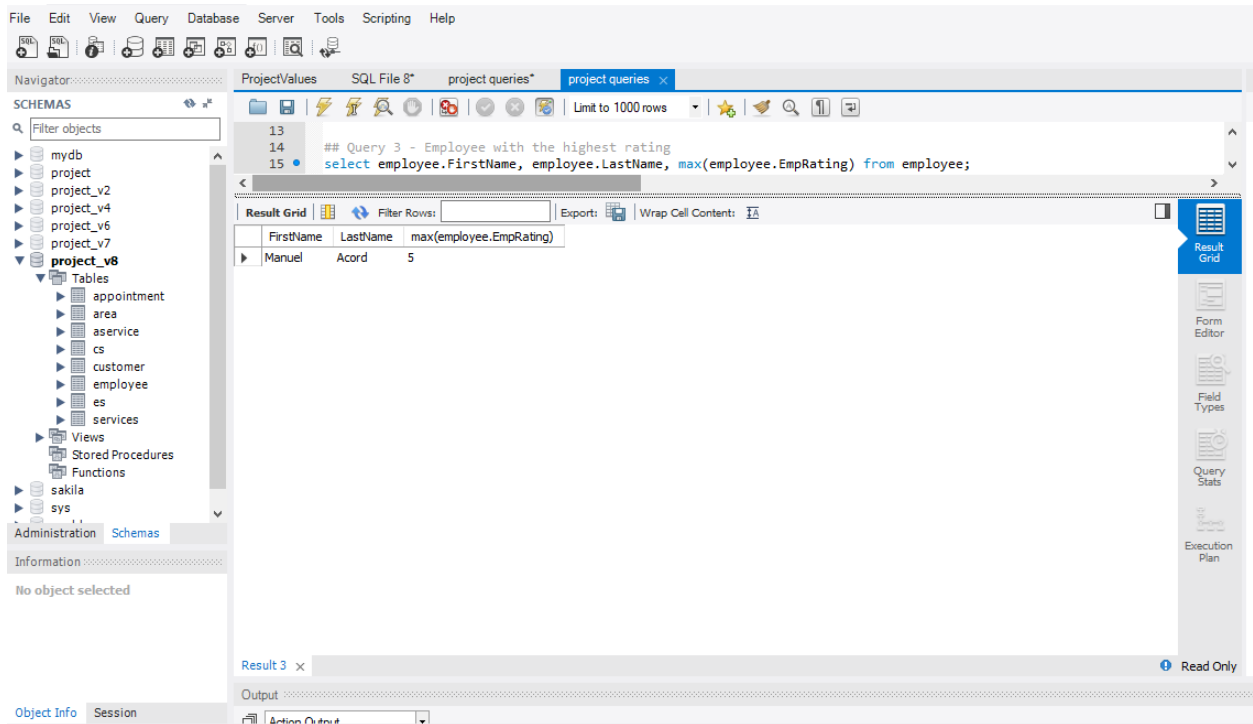

Query 3

Translation – Here we are querying the data to find the employee which has obtained the maximum rating amongst all the other employees.

Example – We will be finding out the maximum rating and appraising the employee. We will be using the 'max' aggregate function. This is a representation of the activity 2

The output generated after executing the query is as follows

Queries in accordance with the Business Process 3 – Business Analysis

Query 4

Translation – Here we will find out the total number of appointments which are placed area wise. This will help us decipher as to which areas show popularity for a particular service.

Example – To decide the popularity we have only displayed count of appointments which are greater than 2 after using the group by function for Area.

The output generated after executing this query is as follows

The screenshot shows a SQL IDE interface with a menu bar (File, Edit, View, Query, Database, Server, Tools, Scripting, Help) and a toolbar. The left pane displays a 'SCHEMAS' tree with a search filter. The tree structure is as follows:

- mydb
 - project
 - project_v2
 - project_v4
 - project_v6
 - project_v7
 - project_v8
 - Tables
 - appointment
 - area
 - aservice
 - cs
 - customer
 - employee
 - es
 - services
 - Views
 - Stored Procedures
 - Functions
 - sakila
 - sys

The main editor shows a SQL query:

```

16
17
18  ## Query 4 - group services greater than 2 in each area where it is applicable
19  select area.AreaCode, area.AreaName, count(services.ServiceId) as service_count
20  from area,aservice,services
21  where area.AreaCode = aservice.Area_AreaCode
22  and aservice.Services_ServiceId = services.ServiceId
23  group by area.AreaCode
24  having service_count > 2;

```

The 'Result Grid' shows the following data:

| AreaCode | AreaName | service_count |
|----------|-------------|---------------|
| 75089 | Rowlett | 4 |
| 75043 | Garland | 3 |
| 75182 | Sunnyvale | 4 |
| 75116 | Duncanville | 3 |
| 75150 | Mesquite | 3 |

The bottom status bar indicates 'Result 4 x' and 'Read Only'.

Query 5

Translation – We will find out our most frequent customers according to the number of appointments they have booked.

Example – We will sort the count of appointments in a descending order to find out our most popular customer. This will further help us to find out the service used most and which we can promote in areas which give us a low revenue.

Output generated after executing the query is as follows

The screenshot shows a database management tool interface. On the left is a 'SCHEMAS' tree with a search bar and a list of databases including 'mydb', 'project', 'project_v2', 'project_v4', 'project_v6', 'project_v7', and 'project_v8'. The 'project_v8' database is selected, showing a list of tables: 'appointment', 'area', 'aservice', 'cs', 'customer', 'employee', 'es', 'services', 'Views', 'Stored Procedures', 'Functions', 'sakila', and 'sys'. The main window displays a SQL query in a text editor:

```

24
25 # Query5 - Which customer has taken the max number of services (best customer)
26 Select c.customerID, c.FirstName, c.LastName, count(s.serviceId) as Total_services_opted
27 from customer c JOIN cs
28 ON c.customerID = cs.Customer_CustomerID
29 JOIN services s
30 ON cs.Services_ServiceId = s.serviceID
31 group by c.customerID
32 order by total_services_opted desc;

```

Below the query editor is a 'Result Grid' showing the results of the query. The grid has four columns: 'customerID', 'FirstName', 'LastName', and 'Total_services_opted'. The results are sorted in descending order of 'Total_services_opted'.

| customerID | FirstName | LastName | Total_services_opted |
|------------|-------------|----------|----------------------|
| 1023 | Sarah | Corner | 20 |
| 1055 | Mia | Harris | 16 |
| 1020 | Sien | Dairy | 16 |
| 1007 | Christopher | Lopez | 16 |
| 1061 | Sofia | Walkar | 16 |
| 1072 | Allen | Dan | 12 |
| 1008 | Yan | Ferry | 12 |
| 1083 | Bass | Coleman | 10 |
| 1100 | Anil | Adams | 10 |
| 1054 | Roshni | Gonzalez | 10 |
| 1051 | Elizabeth | Russel | 10 |
| 1065 | Steven | Paul | 8 |
| 1027 | Clement | Boss | 8 |
| 1092 | Jason | Barnes | 8 |
| 1033 | Emma | Watson | 8 |
| 1099 | Tan | Bobosa | 8 |

On the right side of the interface, there are buttons for 'Result Grid', 'Form Editor', 'Field Types', and 'Query Stats'. The 'Result Grid' button is currently selected.

Queries in accordance with suggestions from the user group regarding this part of our report

Query 6

Translation – Only popularity of a service is not enough for the growth of a particular service. We will check the maximum revenue generated per service to find out which service is the most beneficial to us money wise.

Example – We will be using the aggregate function 'sum' and sort the revenue generated in a descending order per service.

Output generated after executing the query is as follows.

The screenshot shows the SQL Server Enterprise Manager interface. On the left, the 'SCHEMAS' pane displays a tree view of the database structure, including tables like 'appointment', 'area', 'aservice', 'cs', 'customer', 'employee', 'es', 'services', 'Views', 'Stored Procedures', 'Functions', 'sakila', and 'sys'. The 'project_v8' schema is selected. The main pane displays a SQL query in the 'SQL File 8*' tab, which is a query to find the service generating the highest revenue. The query is as follows:

```
# Query 6 - Which service is generating the highest revenue
select services.ServiceId, services.ServiceName, sum(services.ServicePrice) as Revenue_Generated
from appointment, services
where appointment.Services_ServiceId = services.ServiceId
group by services.ServiceId
order by Revenue_Generated desc;
```

The query results are displayed in the 'Result Grid' pane, showing a table with three columns: 'ServiceId', 'ServiceName', and 'Revenue_Generated'. The results are sorted in descending order of revenue generated.

| ServiceId | ServiceName | Revenue_Generated |
|-----------|------------------------|-------------------|
| 1 | AC Service and Repair | 1050 |
| 7 | Electrical Repair | 960 |
| 3 | Washing Machine Repair | 735 |
| 11 | Pest Control | 648 |
| 9 | Carpentering | 620 |
| 4 | Dryer Service | 495 |
| 2 | Refrigerator Repair | 460 |
| 8 | Plumbing | 255 |
| 5 | RO Repair | 180 |
| 10 | Carpet Cleaning | 136 |
| 6 | Microwave Repair | 114 |

Query 7

Translation – Here we will calculate the maximum number of appointments per area which will help us to find out in what area is our business the most popular

Example – We will be using count aggregation and sorting it in a descending manner to find out our most popular area.

Output generated after executing the query is as follows.

Journal detailing interactions with partner user group

We met our reviewer group several times regarding the project work. We also had a talk with our reviewer group regarding the data requirements and functional requirements.

Working together we learnt many different things and got a different outlook which was beneficial towards making our project a technically and professionally sound one.

Most significant outcomings of our interaction were as listed below.

1. We were asked to make the database more sound by using appropriate names for tables and entities.
2. Normalization was not a problem in our database, but they explained us as to why that problem does not exist in our database.
3. They gave excellent recommendations regarding the business processes that we must include, and which ones should we do away with.
4. They provided us with a different prospect regarding our business idea. They gave us tips to make our project look bigger and more realizable.
5. Coming to the reports, they put in efforts to enhance our presentation skills. They asked us to include page numbers and prepare a table of contents.
6. Only after thorough analysis, they gave us a heads up to upload the project on blackboard.

Recommendations provided by User group corresponding to different parts of the report

Part 1

Regarding the nomenclature of the tables in the database.

The user group provided us with certain insights regarding the nomenclature of the tables in our database. We were using vague names for tables at first. We were unsure as to what names would be suitable for the tables which had only used to set the cardinality from many to many to one to many.

Therefore, we changed the table names of the following tables

Appointment & Services → aservice

Customer & Services → cs

Employee & Services → es

This helped us a lot. This makes it easier for the person accessing the database for the first time easier to interpret the working of the database. Naming each table judiciously is important while developing a database.

Part 2

Regarding the cardinality of the entity relationship diagram.

We had initially designed an 'offering table' in order to map the primary keys as foreign keys. The user group asked us to use three different tables for mapping (aservice,es,cs). This enabled us to use the data easily. Querying results was no more difficult.

We decided to change the offering table into three different tables, 'es', 'cs' and 'aservice'. As a result, we could display the results to our business processes' queries properly.

Part 3

We were using primary keys not as auto incrementing integers but as user inputs. This increases the chances of same data being entered. An identical row is not what a database accepts readily, and it then becomes impossible to delete the row. The user group asked us to use auto-incrementing integers.

This was something which we should have thought of earlier. Due to autoincrementing primary keys each record is unique. It takes human error out of the picture. All discrepancies of data cease to exist.

Part 4

Initially we had designed only five queries. The user group came up with two more.

We executed those queries and the results obtained will surely help us to expand our business and making it even more profitable.

In reality, those queries suggested were like different business processes all together.
